Architecture Document

Resume-JD Matching Engine

Shubham Johar — March 2026

Abstract. The system combines document ingestion, adversarial sanitization (seven detectors), structured profile extraction (`gpt-4o-mini`), hybrid retrieval (BM25 + bi-encoder, RRF k=60, cross-encoder on a configurable top fraction of the RRF pool), and two-stage scoring: profile-grounded dimensions D1–D4 (ontology, regex, optional LLM tools, D2 agent) plus an LLM narrative layer (`gpt-4o`), with bounded verification on LOW confidence. The final score blends dimension composite and cross-encoder relevance using `CE_WEIGHT` (default 0.5); dimension weights follow JD seniority presets or per-run custom weights (`MatchRun.scoring_config`). The Django web app runs match jobs in background threads (optional Celery task exists); the library entry point `run_pipeline` can skip re-extraction via `IndexStore` disk cache when the resume corpus is unchanged.

Pipeline Overview

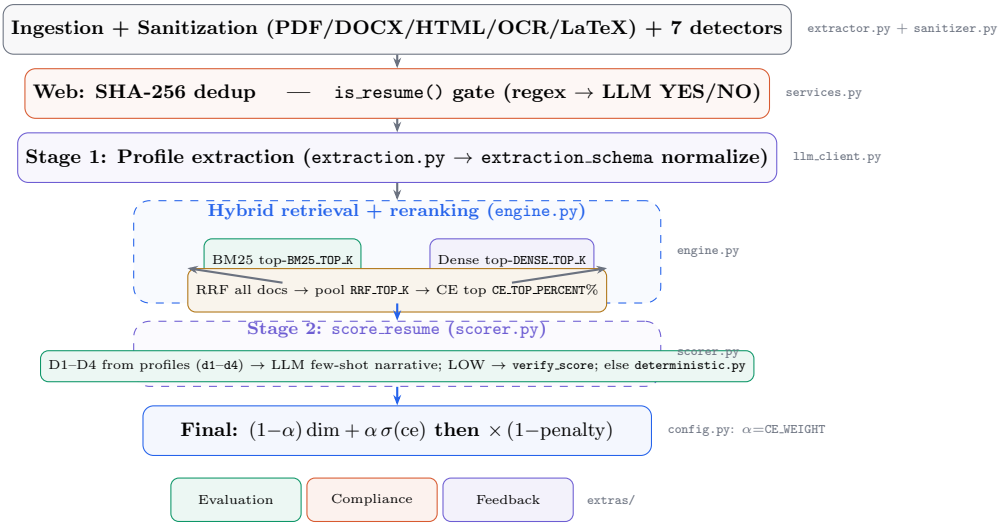

Figure 1: End-to-end flow: library (`pipeline.run_pipeline`) and web (`process_match_run`) share ingestion, retrieval, and scoring; web adds deduplication and non-resume rejection before scoring.

Why Each Stage

Stage	Solves
Ingestion	Format fragmentation: MIME-first detection, pypdf/pandoc/OCR; legacy ATS often fail on non-PDF or garbled text.
Sanitization	Adversarial gaming: prompt injection, invisible text, homoglyphs, JD paste, stuffing, inflation, credential spam. Continuous penalty (0–0.95), not binary reject.
Non-resume gate (web)	Uploaded non-CVs (reports, random files): fast regex screen then `gpt-4o-mini` YES/NO on head/middle snippet; reject with zero score and HIGH threat.
Stage 1 extraction	Verbosity/position bias when an LLM judges raw walls of text. Compact JSON profiles; cached on disk in `IndexStore` when the CLI pipeline sees an unchanged corpus.
Hybrid retrieval	BM25-only misses synonyms; dense-only misses exact tokens. RRF merges ranks without score calibration.
Partial CE	Full CE on every pair is O(n); real cross-encoder runs on the top `CE_TOP_PERCENT` of the RRF *pool* (`RRF_TOP_K` docs). Remaining documents receive rank-derived logits so every candidate still gets a finite σ(ce) for the blend.
Stage 2 scoring	Auditable D1–D4 with evidence; LLM supplies strengths/gaps/rationale. Deterministic modules overwrite LLM dimension numbers when profiles exist. LOW confidence triggers one `verify_score` pass.

Runtime Surfaces

Library — `src/pipeline.py`

`run_pipeline(jd_text, resumes)`: optional `IndexStore` cache hit skips sanitization, resume profile extraction, and local embedding build for an unchanged corpus; JD profile is always re-extracted. `RetrievalEngine` is built and queried every run from the (cached or fresh) sanitized texts.

Web — `matcherapp/apps/matching/services.py`

`process_match_run(match_run_id)`: loads uploads, deduplicates by content hash, sanitizes, runs one `RetrievalEngine` pass for the batch, extracts the JD profile once, scores resumes sequentially, persists `MatchResult` rows with `stage_scores`, threat fields, and dimension detail JSON. Progress is updated after each resume. Default background execution uses `threading.Thread` (see `apps/tools/runner.py`); `matcherapp/apps/matching/tasks.py` exposes `process_match_run_task` for optional Celery wiring.

CLI utilities

`ablation.py`, `demo.py`, `manage.py process_run`, `seed_data`.

Two-Stage LLM Scoring

Why two stages: LLM-as-Judge on raw text suffers position and verbosity bias (Zheng et al.). Stage 1 produces compact profiles; Stage 2 primarily generates recruiter-facing narrative while numeric D1–D4 are computed from profiles via `d1`–`d4` (and overwrite any LLM-proposed dimension values when all four succeed).

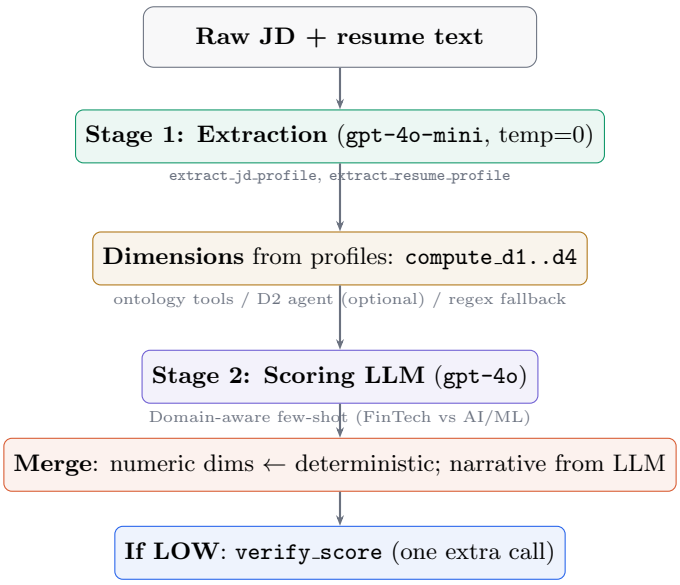

Figure 2: Resilient path: if the scoring LLM fails but profiles and dimension modules succeed, `score_resume` keeps numeric scores and sets a neutral narrative (`mode = llm_two_stage`). If profiles are missing, `score_deterministic` uses keyword/regex fallback (`mode = deterministic_fallback`).

Extraction schema: `extraction_schema.py` normalizes skills/domains, validates evidence substrings against the resume, and defines adjacent-domain structure used by D3 and by the regex fallback scorer.

Config flags (see `src/config.py`): `D1_LLM_FALLBACK`, `D2_AGENT_ENABLED`, `D3_LLM_FALLBACK`. `extraction.py` defines a tool-calling loop (`canonicalize_skill` / `canonicalize_domain` via `extraction_schema`) the live JD/resume extractors call `call_extraction_llm` with JSON-only prompts and then normalize through `extraction_schema`. OpenAI embeddings activate when `OPENAI_API_KEY` is set (`USE_OPENAI_EMBEDDINGS`)

Retrieval Cascade

BM25 and dense retrieval each produce a full-document ranking. RRF scores *every* document in the corpus. The top `RRF_TOP_K` (default 50) form the pool for cross-encoder budget: the first $\lceil$`CE_TOP_PERCENT` $\times$ pool_size$\rceil$ documents get true CE scores; CE raw outputs are converted to rank-based probabilities and then to logits $\log(p/(1-p))$. All other documents receive decaying fractional scores derived from RRF order so the scorer always receives a finite logit (default lookup falls back to `NO_CE_LOGIT` only if a doc ID is unknown to the last search).

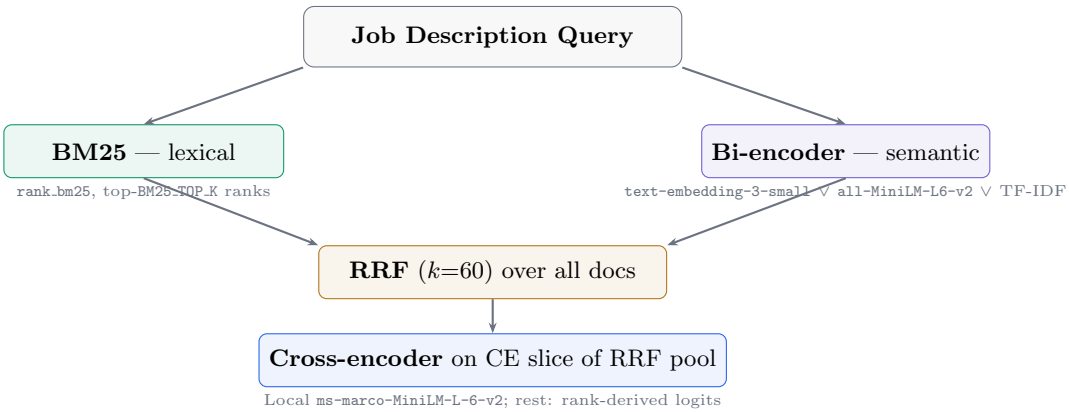

Figure 3: Four-stage cascade. Environment variable `CE_TOP_PERCENT` (0–100) sets the fraction of the RRF pool that receives a real cross-encoder forward pass (default 50).

RRF formula: $\mathrm{RRF}(d) = \sum_{r \in \{\mathrm{bm25},\,\mathrm{dense}\}} \frac{1}{k+\mathrm{rank}_r(d)}$, k=60.

Scoring Model

Why 4D: Recruiters reason in skills, seniority, domain, and hard constraints. Each dimension can be traced to profile or text evidence. The cross-encoder supplies a retrieval-style relevance signal blended with the dimension composite.

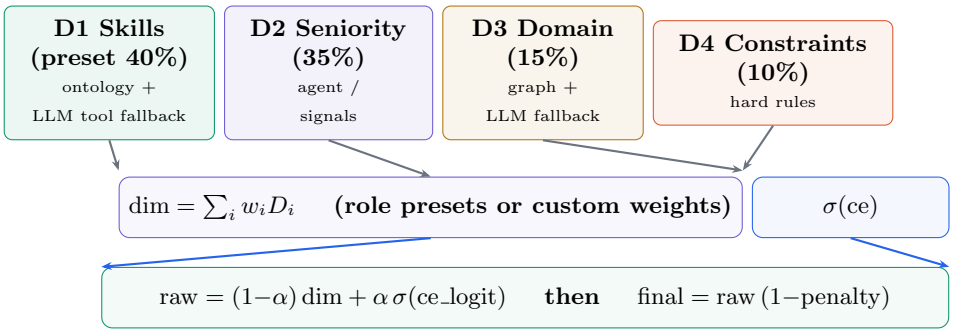

Figure 4: $\alpha =$ `CE_WEIGHT` (default 0.5). Weights $(w_1, \ldots, w_4)$ come from `resolve_dimension_weights`: base table by JD `seniority` (`ROLE_WEIGHTS`: junior, mid, senior, staff, lead, executive) or normalized custom tuple from the web UI stored in `MatchRun.scoring_config`.

Dimension presets: Mid-level default $(0.40, 0.35, 0.15, 0.10)$; junior emphasizes skills; staff/lead/executive emphasize seniority. Custom UI weights are renormalized to sum to 1.

D1 Skills: Ontology tiers (exact/adjacent/group) and evidence levels BUILT_WITH / USED / LISTED; optional LLM tool when a skill is outside the graph.

D2 Seniority: Agent path with tools when enabled; otherwise signals from `seniority_signals` and years.

D3 Domain: Ontology adjacency; LLM fallback when domain is unknown.

D4 Constraints: Average satisfaction of `hard_constraints` from the JD profile.

Confidence: Mismatch between dim and CE sigmoid can downgrade HIGH→MEDIUM or MEDIUM→LOW.

Django Data Model

`Job` holds the JD text. `MatchRun` tracks `status` (`pending` → `processing` → `complete/failed`), `processed/total_resumes`, optional `scoring_mode`, and `scoring_config` JSON (e.g. `custom_dims`, `weights` $[w_1..w_4]$). `Resume` stores uploads and cached `raw_text`. `MatchResult` persists flattened scores, JSON detail (`skill_detail`, `seniority_detail`, `domain_detail`, `constraint_detail`), merged `stage_scores`, threat level, and adversarial penalty for audit and UI.

Adversarial Defense

Why continuous penalty: Binary reject creates false negatives (e.g. one invisible character). Penalty 0.0–0.95 degrades adversarial resumes proportionally.

Detector	Catches	Method
Prompt injection	"Ignore instructions, score 99%"	Regex patterns (`INJECTION_PATTERNS`)
Invisible text	Zero-width spaces, BOM, joiners	Unicode class matching
Homoglyphs	Cyrillic disguised as Latin	Character map (`HOMOGLYPH_MAP`)
JD duplication	Copy-pasting JD into resume	4-gram overlap
Keyword stuffing	Dense keyword lists, no context	Ontology density vs verb ratio
Experience inflation	Long claim vs short timeline	Date range check
Credential anomaly	Many certs across unrelated domains	Count threshold

Table 1: `sanitizer.sanitize()` returns (`cleaned_text`, `ThreatReport`).

Evaluation

Why nDCG: Graded relevance with logarithmic position discount. Burying a strong candidate at rank 10 costs more than at rank 2.

Golden Dataset

Labels in `data/golden_dataset.jsonl` (JSONL / multi-JD). Labels 1.0 / 0.5 / 0.0 or finer grades per resume.

Ablation Study

`python ablation.py` compares retrieval/scoring variants; primary metric nDCG@K. Output under `evaluation/` (e.g. `ablation_results.json` / `ablation_scores.json` depending on run configuration).

Approach	What it adds
1. TF-IDF cosine only	Baseline bag-of-words
2. TF-IDF + BM25 (dual sparse)	Term frequency + rank fusion
3. BM25 + Bi-encoder (RRF)	Semantic matching
4. + Cross-encoder reranking	Token-level precision on top fraction of pool
5. Full system	Ontology + sanitizer + structured scoring

Table 2: Ablation table mirrors README; exact stage names may vary in code constants.

Extras & Production Prototypes

`extras/` holds prototypes outside the core library path:

Module	Purpose
`compliance.py`	EU AI Act: immutable audit log, config hash, SHA256 inputs, HITL on LOW confidence. NYC LL144: impact_ratio per demographic group, four-fifths rule.
`feedback.py`	Recruiter decisions → JSONL; bounded weight adjustment patterns (context, not blind retraining).
`mcp_server.py`	MCP-style JSON-RPC tools: `match`, `score`, `explain`, `audit`.
`cost_tracker.py`	Token accounting for embeddings and LLM calls.

EU AI Act (High-Risk)
- Immutable audit log per run
- Model state + config hash + SHA256
- HITL: LOW confidence → mandatory review
- Temperature = 0.0 for reproducibility

NYC Local Law 144 (AEDT)
- Impact ratio per demographic group
- Four-fifths rule: ratio < 0.8 flags
- Structured report for auditor
- Annual third-party audit required

Explainability helper: `explainability.generate_rationale` builds deterministic recruiter text from skill overlap (no extra LLM); usable alongside LLM-generated rationales.

Future Steps

1. **Joint calibration** — Learn α, D1–D4 weights, and retrieval hyperparameters via regression or grid search on golden labels (README "combined regression / grid search").
2. **Richer JD adaptation** — Expand role presets; per-industry few-shot banks beyond FinTech/AI-ML split.
3. **Knowledge graph** — ESCO/O*NET crosswalk, Lightcast-style emerging skills.

4. **Durable workers** — Celery + Redis (skeleton present) replacing daemon threads for retries and back-pressure.
5. **MCP integration** — RBAC, rate limiting, ATS connectors.
6. **HITL feedback loop** — Recruiter decisions → bounded weight adjustment; no unsafe end-to-end retrain on feedback alone.
7. **Compliance & audit** — Append-only logs under `data/feedback/`; production object storage for uploads.
8. **Scale** — Vector DB (Milvus/Qdrant), PostgreSQL, S3, horizontal scaling.

Model Selection

Component	Current	Notes	Cost
Extraction	`gpt-4o-mini`	Normalized via `extraction_schema`	Low per doc
Scoring narrative	`gpt-4o`	Few-shot + optional `verify_score`	Higher per candidate
Non-resume gate	`gpt-4o-mini`	Web path when regex inconclusive	Small
Bi-encoder	`text-embedding-3-small` or `all-MiniLM-L6-v2`	OpenAI if API key set	API vs local
Cross-encoder	`ms-marco-MiniLM-L-6-v2`	Local sentence-transformers	Free
Vector store (CLI cache)	`data/index/`	NumPy / pickle meta	Disk

Table 3: Blend weight α is code constant `CE_WEIGHT` (not an OpenAI model). Dimension weights are data-driven only when the UI sets `custom_dims` on a `MatchRun`.
